# 1 ABOUT THIS DOCUMENT

## 1.1 Change control

### 1.1.1 Current status and anticipated changes

Issue A-06 of this specification is the *first public release*.

Issue A-08 is the ADS-1.0/1.0.1 release.

Issue B-01 is the ADS-1.1 release.

### 1.1.2 Change history

Issue	Date	By	Change
A-06	5 November 1998	-	Editorial changes following review of final internal DRAFT.
A-07	17 September 1999	-	Added definitions of PF_xx flags, PF_ARM_xxx flags, \$r, \$p, and the EF_ARM_EABIxxx version number. Updated the definition of <i>common section</i> , added descriptions of \$Super\$\$ and \$Sub\$\$ and clarified type-dependent relocation.
A-08	22 September 1999	-	Removed \$r—inadequate for the purpose.
B-01	August-October 2000	-	Simplified and clarified the presentation. Completed the description of shared objects and re-locatable executables.
B-02	8 June 2001	-	Repaired the broken hyperlink to TIS ELF.

## 1.2 References

This document refers to the following document and reproduces book 1 of it as section 3, below.

Ref	Doc No	Author(s)	Title
TIS-ELF	<a href="http://www.x86.org/ftp/manuals/tools/elf.pdf">http://www.x86.org/ftp/manuals/tools/elf.pdf</a>	Tool Interface Standards (TIS) Committee	Executable and Linking Format (ELF) Specification (version 1.2)

## 1.3 Terms and abbreviations

This document uses the following terms and abbreviations.

Term	Meaning
TIS	Tool Interface Standards
ELF	Executable and Linking Format
(E)ABI	(Embedded) Applications Binary Interface
OS	Operating System

## 2 SCOPE

This specification defines ARM Executable and Linking Format (ARM ELF). It follows the essential structure of the Tool Interface Standards (TIS) Committee's version 1.2 specification of ELF (TIS-ELF). TIS-ELF is divided into three major sections that TIS-ELF calls books:

- Book 1 defines generic, 32-bit ELF. All users of 32-bit ELF use the definitions given in book 1. Section 3 of this specification reproduces the content of book 1 of TIS-ELF (Copyright Tool Interface Standards Committee 1995), with a few editorial corrections and clarifications, but no intentional change of content.
- Book 2 defines processor specifics, the definitions used by all users of ELF for a given processor (in the case of TIS-ELF, for the Intel x86 architecture).
- Book 3 defines operating system specifics (in the case of TIS-ELF, for Unix System V.4 for x86).

Section 4 of this specification covers the material of books 2 and 3 of TIS-ELF. It includes:

- ARM- and Thumb-specific definitions needed by all users of ARM ELF.
- ARM- and Thumb-specific definitions relating to the ARM Embedded Applications Binary Interface (EABI).

The ARM EABI underlies many ARM- and Thumb-based operating environments that follow the single address-space model.

Some operating systems—especially those founded on multiple virtual address spaces—define their own conventions for using ARM ELF—especially in relation to shared objects and dynamic linking. These OS-specific definitions extend section 4 of this specification.

## 3 GENERIC 32-BIT ELF

### 3.1 Introduction

Section 3 of this specification describes the object file format called ELF (Executable and Linking Format). There are three main types of object files:

- A *re-locatable file* holds code and data suitable for linking with other object files to create an executable or a shared object file.
- An *executable file* holds a program suitable for execution.
- A *shared object file* holds code and data suitable for linking in two contexts. First, the link editor may process it with other re-locatable and shared object files to create another object file. Second, the dynamic linker combines it with an executable file and other shared objects to create a process image.

Created by an assembler or compiler and link editor, object files are binary representations of programs intended to execute directly on a processor. Programs that require other abstract machines are excluded.

After the introductory material, this section focuses on the file format and how it pertains to building programs. Subsections 3.7 onwards describe those parts of the object file containing the information necessary to execute a program.

#### 3.1.1 File Format

Object files participate in program linking (building a program) and program execution (running a program). For convenience and efficiency, the object file format provides parallel views of a file's contents, reflecting the differing needs of these activities. Figure 3-1 below shows an object file's organization.

**Figure 3-1, Object file format**

Linking View	Execution View
ELF Header	ELF Header
Program Header Table <i>optional</i>	Program Header Table
Section 1	Segment 1
...	
Section n	Segment 2
...	
...	...
Section Header Table	Section Header Table <i>optional</i>

An *ELF header* resides at the beginning and holds a *road map* describing the file's organization. Sections hold the bulk of object file information for the linking view: instructions, data, symbol table, relocation information, and so on. Descriptions of special sections appear later in this section. Subsections 3.7 onwards describe segments and the program execution view of the file.

A *program header table*, if present, tells the system how to create a process image. Files used to build a process image (execute a program) must have a program header table; re-locatable files do not need one. A *section header table* contains information describing the file's sections. Every section has an entry in the table; each entry gives information such as the section name, the section size, and so on. Files used during linking must have a section header table; other object files may or may not have one.

**Note** Although the figure shows the program header table immediately after the ELF header, and the section header table following the sections, actual files may differ. Moreover, sections and segments have no specified order. Only the ELF header has a fixed position in the file.

### 3.1.2 Data Representation

As described here, the object file *format* supports various processors with 8-bit bytes and 32-bit architectures. Nevertheless, it is intended to be extensible to larger (or smaller) architectures. Object files therefore represent some control data with a machine-independent format, making it possible to identify object files and interpret their contents in a common way. Remaining data in an object file use the encoding of the target processor, regardless of the machine on which the file was created.

**Figure 3-2, 32-Bit Data Types**

Name	Size	Alignment	Purpose
Elf32_Addr	4	4	Unsigned program address
Elf32_Half	2	2	Unsigned medium integer
Elf32_Off	4	4	Unsigned file offset
Elf32_Sword	4	4	Signed large integer
Elf32_Word	4	4	Unsigned large integer
unsigned char	1	1	Unsigned small integer

All data structures that the object file format defines follow the natural size and alignment guidelines for the relevant class. If necessary, data structures contain explicit padding to ensure 4-byte alignment for 4-byte objects, to force structure sizes to a multiple of 4, and so on. Data also have suitable alignment from the beginning of the file. Thus, for example, a structure containing an Elf32\_Addr member will be aligned on a 4-byte boundary within the file.

For portability reasons, ELF uses no bit fields.

### 3.1.3 Character Representations

This section describes the default ELF character representation and defines the standard character set used for external files that should be portable among systems. Several external file formats represent control information with characters. These single-byte characters use the 7-bit ASCII character set. In other words, when the ELF interface document mentions character constants, such as, `'/'` or `'\n'` their numerical values should follow the 7-bit ASCII guidelines. For the previous character constants, the single-byte values would be 47 and 10, respectively.

Character values outside the range of 0 to 127 may occupy one or more bytes, according to the character encoding. Applications can control their own character sets, using different character set extensions for different languages as appropriate. Although TIS-conformance does not restrict the character sets, they generally should follow some simple guidelines:

- Character values between 0 and 127 should correspond to the 7-bit ASCII code. That is, character sets with encodings above 127 should include the 7-bit ASCII code as a subset.

- ❑ Multi-byte character encodings with values above 127 should contain only bytes with values outside the range of 0 to 127. That is, a character set that uses more than one byte per character should not embed a byte resembling a 7-bit ASCII character within a multi-byte, non-ASCII character.
- ❑ Multi-byte characters should be self-identifying. That allows, for example, any multi-byte character to be inserted between any pair of multi-byte characters, without changing the characters' interpretations.

These cautions are particularly relevant for multilingual applications.

**Note** There are naming conventions for ELF constants that have processor ranges specified. Names such as DT\_, PT\_, for processor specific extensions, incorporate the name of the processor: DT\_M32\_SPECIAL, for example. However, pre-existing processor extensions not using this convention will be supported.

### Pre-existing Extensions

DT\_JMP\_REL

## 3.2 ELF Header

Some object file control structures can grow, because the ELF header contains their actual sizes. If the object file format changes, a program may encounter control structures that are larger or smaller than expected. Programs might therefore ignore extra information. The treatment of missing information depends on context and will be specified when and if extensions are defined.

**Figure 3-3, ELF Header**

```
#define EI_NIDENT 16

typedef struct {
    unsigned char e_ident[EI_NIDENT];
    Elf32_Half e_type;
    Elf32_Half e_machine;
    Elf32_Word e_version;
    Elf32_Addr e_entry;
    Elf32_Off e_phoff;
    Elf32_Off e_shoff;
    Elf32_Word e_flags;
    Elf32_Half e_ehsize;
    Elf32_Half e_phentsize;
    Elf32_Half e_phnum;
    Elf32_Half e_shentsize;
    Elf32_Half e_shnum;
    Elf32_Half e_shstrndx;
} Elf32_Ehdr;
```

**e\_ident**—The initial bytes mark the file as an object file and provide machine-independent data with which to decode and interpret the file's contents. Complete descriptions appear below, in section 3.2.1, *ELF Identification*.

**E\_type**—This member identifies the object file type.

Name	Value	Meaning
ET_NONE	0	No file type
ET_REL	1	Re-locatable file
ET_EXEC	2	Executable file
ET_DYN	3	Shared object file

***E\_type*** (continued)

Name	Value	Meaning
ET_CORE	4	Core file
ET_LOPROC	0xff00	Processor-specific
ET_HIPROC	0xffff	Processor-specific

Although the core file contents are unspecified, type ET\_CORE is reserved to mark the file type. Values from ET\_LOPROC through ET\_HIPROC (inclusive) are reserved for processor-specific semantics. Other values are reserved and will be assigned to new object file types as necessary.

***E\_machine***—This member's value specifies the required architecture for an individual file.

Name	Value	Meaning
EM_NONE	0	No machine
EM_M32	1	AT&T WE 32100
EM_SPARC	2	SPARC
EM_386	3	Intel Architecture
EM_68K	4	Motorola 68000
EM_88K	5	Motorola 88000
EM_860	7	Intel 80860
EM_MIPS	8	MIPS RS3000 Big-Endian
EM_MIPS_RS4_BE	10	MIPS RS4000 Big-Endian
...	...	...
EM_ARM	40	ARM/Thumb Architecture

Other values are reserved and will be assigned to new machines as necessary. Processor-specific ELF names use the machine name to distinguish them. For example, the flags mentioned below use the prefix EF\_; a flag named WIDGET for the EM\_XYZ machine would be called EF\_XYZ\_WIDGET.

***E\_version***—This member identifies the object file version.

Name	Value	Meaning
EV_NONE	0	Invalid version
EV_CURRENT	1	Current version

The value 1 signifies the original file format; extensions will create new versions with higher numbers. The value of EV\_CURRENT, though given as 1 above, will change as necessary to reflect the current version number.

***E\_entry***—This member gives the virtual address to which the system first transfers control, thus starting the process. If the file has no associated entry point, this member holds zero.

***E\_phoff***—This member holds the program header table's file offset in bytes. If the file has no program header table, this member holds zero.

***E\_shoff***—This member holds the section header table's file offset in bytes. If the file has no section header table, this member holds zero.

***E\_flags***—This member holds processor-specific flags associated with the file. Flag names take the form `EF_machine_flag`. See section 4.1, *ELF header*, for definitions of flag values.

***E\_ehsize***—This member holds the ELF header's size in bytes.

***E\_phentsize***—This member holds the size in bytes of one entry in the file's program header table; all entries are the same size.

***E\_phnum***—This member holds the number of entries in the program header table. Thus the product of `e_phentsize` and `e_phnum` gives the table's size in bytes. If a file has no program header table, `e_phnum` holds the value zero.

***E\_shentsize***—This member holds a section header's size in bytes. A section header is one entry in the section header table; all entries are the same size.

***E\_shnum***—This member holds the number of entries in the section header table. Thus the product of `e_shentsize` and `e_shnum` gives the section header table's size in bytes. If a file has no section header table, `e_shnum` holds the value zero.

***E\_shstrndx***—This member holds the section header table index of the entry associated with the section name string table. If the file has no section name string table, this member holds the value `SHN_UNDEF`. See section 3.3, *Sections* and section 3.4, *String Table* below for more information.

### 3.2.1 ELF Identification

As mentioned above, ELF provides an object file framework to support multiple processors, multiple data encodings, and multiple classes of machines. To support this object file family, the initial bytes of the file specify how to interpret the file, independent of the processor on which the inquiry is made and independent of the file's remaining contents.

The initial bytes of an ELF header (and an object file) correspond to the `e_ident` member.

**Figure 3-4, `e_ident[]` Identification Indexes**

Name	Value	Purpose
EI_MAG0	0	File identification
EI_MAG1	1	File identification
EI_MAG2	2	File identification
EI_MAG3	3	File identification
EI_CLASS	4	File class
EI_DATA	5	Data encoding
EI_VERSION	6	File version
EI_PAD	7	Start of padding bytes
EI_NIDENT	16	Size of <code>e_ident[]</code>

These indexes access bytes that hold the values defined in the following tables.

**EI\_MAG0 to EI\_MAG3**—A file's first 4 bytes hold a *magic number*, identifying the file as an ELF object file.

Name	Value	Meaning
ELFMAG0	0x7f	e_ident[EI_MAG0]
ELFMAG1	ASCII 'E'	e_ident[EI_MAG1]
ELFMAG2	ASCII 'L'	e_ident[EI_MAG2]
ELFMAG3	ASCII 'F'	e_ident[EI_MAG3]

**EI\_CLASS**—The next byte, e\_ident[EI\_CLASS], identifies the file's class, or capacity.

Name	Value	Meaning
ELFCLASSNONE	0	Invalid class
ELFCLASS32	1	32-bit objects
ELFCLASS64	2	64-bit objects

The file format is designed to be portable among machines of various sizes, without imposing the sizes of the largest machine on the smallest. Class ELFCLASS32 supports machines with files and virtual address spaces up to 4 gigabytes; it uses the basic types defined above.

Class ELFCLASS64 is incomplete and refers to the 64-bit architectures. Its appearance here shows how the object file may change. Other classes will be defined as necessary, with different basic types and sizes for object file data.

**EI\_DATA**—Byte e\_ident[EI\_DATA] specifies the data encoding of *all* data<sup>1</sup> in the object file. The following encodings are currently defined.

Name	Value	Meaning
ELFDATANONE	0	Invalid data encoding
ELFDATA2LSB	1	See <i>Data encodings ELFDATA2LSB</i> , below
ELFDATA2MSB	2	See <i>Data encodings ELFDATA2MSB</i> , below

More information on these encodings appears below in Figure 3-5 and Figure 3-6. Other values are reserved and will be assigned to new encodings as necessary.

**EI\_VERSION**—Byte e\_ident[EI\_VERSION] specifies the ELF header version number. Currently, this value must be EV\_CURRENT, as explained above for e\_version.

**EI\_PAD**—This value marks the beginning of the unused bytes in e\_ident. These bytes are reserved and set to zero; programs that read object files should ignore them. The value of EI\_PAD will change in the future if currently unused bytes are given meanings.

A file's data encoding specifies how to interpret the basic objects in a file. As described above, class ELFCLASS32 files use objects that occupy 1, 2, and 4 bytes. Under the defined encodings, objects are represented as shown below. Byte numbers appear in the upper left corners.

---

<sup>1</sup> ELF files for embedded targets contain 3 kinds of data—data intended for the target (e.g. code), data intended for the host (e.g. debug tables), and format-related data (e.g. ELF structures). ARM ELF uniformly uses the byte order of the execution environment for each kind.

Figure 3-5, Data encodings ELFDATA2LSB

Encoding ELFDATA2LSB specifies 2's complement values, with the least significant byte at the lowest address.

Figure 3-6, Data encodings ELFDATA2MSB

Encoding ELFDATA2MSB specifies 2's complement values, with the most significant byte at the lowest address.

### 3.3 Sections

An object file's section header table lets one locate all the file's sections. The section header table is an array of `Elf32_Shdr` structures as described below in Figure 3-8. A section header table index is a subscript into this array. The ELF header's `e_shoff` member gives the byte offset from the beginning of the file to the section header table; `e_shnum` tells how many entries the section header table contains; `e_shentsize` gives the size in bytes of each entry.

Some section header table indexes are reserved; an object file will not have sections for these special indexes.

Figure 3-7, Special Section Indexes

Name	Value
SHN_UNDEF	0
SHN_LORESERVE	0xff00

**Special Section Indexes (continued)**

SHN_LOPROC	0xff00
SHN_HIPROC	0xff1f
SHN_ABS	0xffff1
SHN_COMMON	0xffff2
SHN_HIRESERVE	0xfffff

**SHN\_UNDEF**—This value marks an undefined, missing, irrelevant, or otherwise meaningless section reference. For example, a symbol “defined” relative to section number SHN\_UNDEF is an undefined symbol.

**Note** Although index 0 is reserved as the undefined value, the section header table contains an entry for it. Consequently, if the e\_shnum member of the ELF header says a file has 6 entries in the section header table, they have indexes 0 through 5. The contents of the initial entry are specified in Figure 3-10, below.

**SHN\_LORESERVE**—This value specifies the lower bound of the range of reserved indexes.

**SHN\_LOPROC** through **SHN\_HIPROC**—Values in this range are reserved for processor-specific semantics.

**SHN\_ABS**—This value specifies absolute values for the corresponding reference. For example, symbols defined relative to section number SHN\_ABS have absolute values and are not affected by relocation.

**SHN\_COMMON**—Symbols defined relative to this section are common symbols, such as FORTRAN COMMON or unallocated C external variables.

**SHN\_HIRESERVE**—This value specifies the upper bound of the range of reserved indexes. The system reserves indexes between SHN\_LORESERVE and SHN\_HIRESERVE, inclusive; the values do not refer to the section header table. That is, the section header table does *not* contain entries for the reserved indexes.

Sections contain all information in an object file, except the ELF header, the program header table, and the section header table. Moreover, object files’ sections satisfy several conditions.

- Every section in an object file has exactly one section header describing it. Section headers may exist that do not have a section.
- Each section occupies one contiguous (possibly empty) sequence of bytes within a file.
- Sections in a file may not overlap. No byte in a file resides in more than one section.
- An object file may have inactive space. The various headers and the sections might not cover every byte in an object file. The contents of the inactive data are unspecified.

**Figure 3-8, Section Header**

A section header has the following structure.

```

typedef struct {
    Elf32_Word sh_name;
    Elf32_Word sh_type;
    Elf32_Word sh_flags;
    Elf32_Addr sh_addr;
    Elf32_Off  sh_offset;
    Elf32_Word sh_size;
    Elf32_Word sh_link;
    Elf32_Word sh_info;
    Elf32_Word sh_addralign;
    Elf32_Word sh_entsize;
} Elf32_Shdr;

```

**sh\_name**—This member specifies the name of the section. Its value is an index into the section header string table section [see section 3.4, *String Table* below], giving the location of a null-terminated string.

**Sh\_type**—This member categorizes the section's contents and semantics. Section types and their descriptions appear in Figure 3-9 below.

**Sh\_flags**—Sections support 1-bit flags that describe miscellaneous attributes. Flag definitions appear in Figure 3-11, below.

**Sh\_addr**—If the section will appear in the memory image of a process, this member gives the address at which the section's first byte should reside. Otherwise, the member contains 0.

**Sh\_offset**—This member's value gives the byte offset from the beginning of the file to the first byte in the section. One section type, SHT\_NOBITS described in Figure 3-9 below, occupies no space in the file, and its sh\_offset member locates the conceptual placement in the file.

**Sh\_size**—This member gives the section's size in bytes. Unless the section type is SHT\_NOBITS, the section occupies sh\_size bytes in the file. A section of type SHT\_NOBITS may have a non-zero size, but it occupies no space in the file.

**Sh\_link**—This member holds a section header table index link, whose interpretation depends on the section type. Figure 3-12 below describes the values.

**Sh\_info**—This member holds extra information, whose interpretation depends on the section type. Figure 3-12 below describes the values.

**Sh\_addralign**—Some sections have address alignment constraints. For example, if a section holds a double-word, the system must ensure double-word alignment for the entire section. That is, the value of sh\_addr must be congruent to 0, modulo the value of sh\_addralign. Currently, only 0 and positive integral powers of two are allowed. Values 0 and 1 mean the section has no alignment constraints.

**Sh\_entsize**—Some sections hold a table of fixed-size entries, such as a symbol table. For such a section, this member gives the size in bytes of each entry. The member contains 0 if the section does not hold a table of fixed-size entries. A section header's sh\_type member specifies the section's semantics.

**Figure 3-9, Section Types, sh\_type**

Name	Value	Meaning
SHT_NULL	0	This value marks a section header that does not have an associated section. Other members of the section header have undefined values
SHT_PROGBITS	1	The section holds information defined by the program, whose format and meaning are determined solely by the program.
SHT_SYMTAB	2	The section holds a symbol table.
SHT_STRTAB	3	The section holds a string table.
SHT_RELA	4	The section holds relocation entries with explicit addends, such as type Elf32_Rela for the 32-bit class of object files. An object file may have multiple relocation sections. See <i>Relocation</i> below for details.
SHT_HASH	5	The section holds a symbol hash table.
SHT_DYNAMIC	6	The section holds information for dynamic linking.
SHT_NOTE	7	This section holds information that marks the file in some way.

**Section Types, *sh\_type* (continued)**

SHT_NOBITS	8	A section of this type occupies no space in the file but otherwise resembles SHT_PROGBITS. Although this section contains no bytes, the <i>sh_offset</i> member contains the conceptual file offset.
SHT_REL	9	The section holds relocation entries without explicit addends, such as type Elf32_Rel for the 32-bit class of object files. An object file may have multiple relocation sections. See <i>Relocation</i> below for details.
SHT_SHLIB	10	This section type is reserved but has unspecified semantics.
SHT_DYNSYM	11	The section holds a symbol table.
SHT_LOPROC	0x70000000	Values in this inclusive range are reserved for processor-specific semantics.
SHT_HIPROC	0x7fffffff	
SHT_LOUSER	0x80000000	Values in this inclusive range are reserved for application programs. Types between SHT_LOUSER and SHT_HIUSER may be used by an application, without conflicting with current or future system-defined section types.
SHT_HIUSER	0xffffffff	

As mentioned before, the section header for index 0 (SHN\_UNDEF) exists, even though the index marks undefined section references. This entry holds the following.

**Figure 3-10, Section Header Table Entry: Index 0**

Name	Value	Note
<i>sh_name</i>	0	No name
<i>sh_type</i>	SHT_NULL	Inactive
<i>sh_flags</i>	0	No flags
<i>sh_addr</i>	0	No address
<i>sh_offset</i>	0	No file offset
<i>sh_size</i>	0	No size
<i>sh_link</i>	SHN_UNDEF	No link information
<i>sh_info</i>	0	No auxiliary information
<i>sh_addralign</i>	0	No alignment
<i>sh_entsize</i>	0	No entries

A section header's *sh\_flags* member holds 1-bit flags that describe the section's attributes. Defined values are shown in Figure 3-11 below; other values are reserved.

**Figure 3-11, Section Attribute Flags, *sh\_flags***

Name	Value	Meaning
SHF_WRITE	0x1	The section contains data that should be writable during process execution
SHF_ALLOC	0x2	The section occupies memory during process execution. Some control sections do not reside in the memory image of an object file; this attribute is off for those sections
SHF_EXECINSTR	0x4	The section contains executable machine instructions.
SHF_MASKPROC	0xf0000000	Bits in this mask are reserved for processor-specific semantics.

If a flag bit is set in *sh\_flags*, the attribute is *on* for the section. Otherwise, the attribute is *off* or does not apply. Reserved attributes are set to zero.

Two section header members, *sh\_link* and *sh\_info*, hold special information, depending on section type.

**Figure 3-12, *sh\_link* and *sh\_info* Interpretation**

sh_type	sh_link	sh_info
SHT_DYNAMIC	The section header index of the string table used by entries in the section.	0
SHT_HASH	The section header index of the symbol table to which the hash-table applies.	0
SHT_REL SHT_RELA	The section header index of the associated symbol table.	The section header index of the section to which the relocation applies.
SHT_SYMTAB SHT_DYNSYM	This information is operating system specific.	This information is operating system specific.
Other	SHN_UNDEF	0

### 3.3.1 Special Sections

Various sections in ELF are pre-defined and hold program and control information. These sections are used by the operating system and have different types and attributes for different operating systems.

Executable files are created from individual object files and libraries through the linking process. The linker resolves the references (including subroutines and data references) among the different object files, adjusts the absolute references in the object files, and relocates instructions. The linking and loading processes, which are described in subsections 3.7 onwards, require information defined in the object files and store this information in specific sections such as *.dynamic*.

Each operating system supports a set of linking models, which fall into two categories:

- ❑ **Static.** A set of object files, system libraries and library archives are statically bound, references are resolved, and an executable file is created that is completely self contained.
- ❑ **Dynamic.** A set of object files, libraries, system shared resources and other shared libraries are linked together to create the executable. When this executable is loaded, other shared resources and dynamic libraries must be made available in the system for the program to run successfully.

The general method used to resolve references at execution time for a dynamically linked executable file is described in the linkage model used by the operating system, and the actual implementation of this linkage model will contain processor-specific components (see section 4, *ARM- and Thumb-Specific Definitions*).

There are also sections that support debugging, such as `.debug` and `.line`, and program control, including `.bss`, `.data`, `.data1`, `.rodata`, and `.rodata1`.

**Figure 3-13, Special Sections**

Name	Type	Attributes
<code>.bss</code>	SHT_NOBITS	SHF_ALLOC+SHF_WRITE
<code>.comment</code>	SHT_PROGBITS	none
<code>.data</code>	SHT_PROGBITS	SHF_ALLOC + SHF_WRITE
<code>.data1</code>	SHT_PROGBITS	SHF_ALLOC + SHF_WRITE
<code>.debug</code>	SHT_PROGBITS	none
<code>.dynamic</code>	SHT_DYNAMIC	see below
<code>.hash</code>	SHT_HASH	SHF_ALLOC
<code>.line</code>	SHT_PROGBITS	none
<code>.note</code>	SHT_NOTE	None
<code>.rodata</code>	SHT_PROGBITS	SHF_ALLOC
<code>.rodata1</code>	SHT_PROGBITS	SHF_ALLOC
<code>.shstrtab</code>	SHT_STRTAB	None
<code>.strtab</code>	SHT_STRTAB	see below
<code>.symtab</code>	SHT_SYMTAB	see below
<code>.text</code>	SHT_PROGBITS	SHF_ALLOC + SHF_EXECINSTR

**.bss**—This section holds uninitialized data that contribute to the program's memory image. By definition, the system initializes the data with zeros when the program begins to run. The section occupies no file space, as indicated by the section type, SHT\_NOBITS.

**.comment**—This section holds version control information.

**.data** and **.data1**—These sections hold initialized data that contribute to the program's memory image.

**.debug**—This section holds information for symbolic debugging. The contents are unspecified. All section names with the prefix `.debug` are reserved for future use.

**.dynamic**—This section holds dynamic linking information and has attributes such as SHF\_ALLOC and SHF\_WRITE. The operating system and processor determine whether the SHF\_WRITE bit is set.

**.hash**—This section holds a symbol hash table.

**.line**—This section holds line number information for symbolic debugging, which describes the correspondence between the source program and the machine code. The contents are unspecified.

**.note**—This section holds information in the format that is described in section 3.7.2, *Note Section*, below.

**.rodata** and **.rodata1**—These sections hold read-only data that typically contribute to a non-writable segment in the process image. See *Program Header* in subsection 3.7.1 for more information.

**.shstrtab**—This section holds section names.

**.strtab**—This section holds strings, most commonly only the strings that represent the names associated with symbol table entries. If a file has a loadable segment that includes the symbol string table, the section's attributes will include the SHF\_ALLOC bit; otherwise, that bit will be off.

**.symtab**—This section holds a symbol table, described in section 3.5. If a file has a loadable segment that includes the symbol table, the section's attributes will include the SHF\_ALLOC bit; otherwise, that bit will be off.

**.text**—This section holds the text, or executable instructions, of a program.

Section names with a dot (.) prefix are reserved for the system, although applications may use these sections if their existing meanings are satisfactory. Applications may use names without the prefix to avoid conflicts with system sections. The object file format lets one define sections not in the list above. An object file may have more than one section with the same name.

### 3.4 String Table

This section describes the default string table. String table sections hold null-terminated character sequences, commonly called strings. The object file uses these strings to represent symbol and section names. One references a string as an index into the string table section. The first byte, which is index zero, is defined to hold a null character. Likewise, a string table's last byte is defined to hold a null character, ensuring null termination for all strings. A string whose index is zero specifies either no name or a null name, depending on the context. An empty string table section is permitted; its section header's `sh_size` member would contain zero. Non-zero indexes are invalid for an empty string table.

A section header's `sh_name` member holds an index into the section header's string table section, as designated by the `e_shstrndx` member of the ELF header. The following figures show a string table with 25 bytes and the strings associated with various indexes.

Index	+0	+1	+2	+3	+4	+5	+6	+7	+8	+9
0	\0	n	a	M	e	.	\0	V	a	r
10	l	a	b	L	e	\0	a	b	l	e
20	\0	\0	x	X	\0					

**Figure 3-14, String Table Indexes**

Index	String
0	none
1	name.
7	Variable
11	able
16	able
24	null string

As the example shows, a string table index may refer to any byte in the section. A string may appear more than once; references to sub-strings may exist; and a single string may be referenced multiple times. Unreferenced strings also are allowed.

### 3.5 Symbol Table

An object file's symbol table holds information needed to locate and relocate a program's symbolic definitions and references. A symbol table index is a subscript into this array. Index 0 both designates the first entry in the table and serves as the undefined symbol index. The contents of the initial entry are specified in Figure 3-18, below.

Index Name	Index Value
STN_UNDEF	0

**Figure 3-15, Symbol Table Entry**

```
typedef struct {
    Elf32_Word st_name;
    Elf32_Addr st_value;
    Elf32_Word st_size;
    unsigned char st_info;
    unsigned char st_other;
    Elf32_Half st_shndx;
} Elf32_Sym;
```

**st\_name**—This member holds an index into the object file's symbol string table, which holds the character representations of the symbol names.

**st\_value**—This member gives the value of the associated symbol. Depending on the context this may be an absolute value, an address, and so on; details are given in section 3.5.1, *Symbol Values* below.

**st\_size**—Many symbols have associated sizes. For example, a data object's size is the number of bytes contained in the object. This member holds 0 if the symbol has no size or an unknown size.

**st\_info**—This member specifies the symbol's type and binding attributes. A list of the values and meanings appears in Figure 3-16 and Figure 3-17, below. The following code shows how to manipulate the values.

```
#define ELF32_ST_BIND(i) ((i)>>4)
#define ELF32_ST_TYPE(i) ((i)&0xf)
#define ELF32_ST_INFO(b,t) (((b)<<4)+(t)&0xf))
```

**st\_other**—This member currently holds 0 and has no defined meaning.

**st\_shndx**—Every symbol table entry is “defined” in relation to some section; this member holds the relevant section header table index. As Figure 3-7 above and subsection 3.3.1 above describe, some section indexes indicate special meanings.

A symbol's binding determines the linkage visibility and behavior.

**Figure 3-16, Symbol Binding, ELF32\_ST\_BIND**

Name	Value
STB_LOCAL	0
STB_GLOBAL	1
STB_WEAK	2

**Symbol Binding, ELF32\_ST\_BIND (continued)**

STB_LOPROC	13
STB_HIPROC	15

**STB\_LOCAL**—Local symbols are not visible outside the object file containing their definition. Local symbols of the same name may exist in multiple files without interfering with each other.

**STB\_GLOBAL**—Global symbols are visible to all object files being combined. One file's definition of a global symbol will satisfy another file's undefined reference to the same global symbol.

**STB\_WEAK**—Weak symbols resemble global symbols, but their definitions have lower precedence. Undefined weak symbols (weak references) may have processor- or OS-specific semantics (see, for example, section 4.4.3, *Weak symbols*).

**STB\_LOPROC** through **STB\_HIPROC**—Values in this inclusive range are reserved for processor-specific semantics.

In each symbol table, all symbols with STB\_LOCAL binding precede the weak and global symbols. A symbol's type provides a general classification for the associated entity.

**Figure 3-17, Symbol Types, ELF32\_ST\_TYPE**

Name	Value	Meaning
STT_NOTYPE	0	The symbol's type is not specified.
STT_OBJECT	1	The symbol is associated with a data object, such as a variable, an array, and so on.
STT_FUNC	2	The symbol is associated with a function or other executable code.
STT_SECTION	3	The symbol is associated with a section. Symbol table entries of this type exist primarily for relocation and normally have STB_LOCAL binding.
STT_FILE	4	A file symbol has STB_LOCAL binding, its section index is SHN_ABS, and it precedes the other STB_LOCAL symbols for the file, if it is present.
STT_LOPROC	13	Values in this inclusive range are reserved for processor-specific semantics. If a symbol's value refers to a specific location within a section, its section index member, st_shndx, holds an index into the section header table. As the section moves during relocation, the symbol's value changes as well, and references to the symbol continue to point to the same location in the program. Some special section index values give other semantics.
STT_HIPROC	15	

The symbols in ELF object files convey specific information to the linker and loader. See section 4, *ARM- and Thumb-Specific Definitions*, for a description of the actual linking model used in the system.

**SHN\_ABS**—The symbol has an absolute value that will not change because of relocation.

**SHN\_COMMON**—The symbol labels a common block that has not yet been allocated. The symbol's value gives alignment constraints, similar to a section's sh\_addralign member. That is, the link editor will allocate the storage for the symbol at an address that is a multiple of st\_value. The symbol's size tells how many bytes are required.

**SHN\_UNDEF**—This section table index means the symbol is undefined. When the link editor combines this object file with another that defines the indicated symbol, this file's references to the symbol will be linked to the actual definition.

As mentioned above, the symbol table entry for index 0 (STN\_UNDEF) is reserved. It is shown in Figure 3-18.

**Figure 3-18, Symbol Table Entry: Index 0**

Name	Value	Note
st_name	0	No name
st_value	0	Zero value
st_size	0	No size
st_info	0	No type, local binding
st_other	0	
st_shndx	SHN_UNDEF	No section

### 3.5.1 Symbol Values

Symbol table entries for different object file types have slightly different interpretations for the `st_value` member.

- In relocatable files, `st_value` holds alignment constraints for a symbol whose section index is `SHN_COMMON`.
- In relocatable files, `st_value` holds a section offset for a defined symbol. That is, `st_value` is an offset from the beginning of the section that `st_shndx` identifies.
- In executable and shared object files, `st_value` holds a virtual address<sup>1</sup>. To make these files' symbols more useful to the dynamic linker, the section offset (file interpretation) gives way to a virtual address (memory interpretation) for which the section number is irrelevant.

Although the symbol table values have similar meanings for different object files, the data allow efficient access by the appropriate programs.

## 3.6 Relocation

Relocation is the process of connecting symbolic references with symbolic definitions. For example, when a program calls a function, the associated call instruction must transfer control to the proper destination address at execution. In other words, relocatable files must have information that describes how to modify their section contents, thus allowing executable and shared object files to hold the right information for a process's program image. *Relocation entries* are these data.

**Figure 3-19 Relocation Entries**

```

typedef struct {
    Elf32_Addr r_offset;
    Elf32_Word r_info;
} Elf32_Rel;

typedef struct {
    Elf32_Addr r_offset;
    Elf32_Word r_info;
    Elf32_Sword r_addend;
} Elf32_Rela;

```

**r\_offset**—This member gives the location at which to apply the relocation action. For a relocatable file, the value is the byte offset from the beginning of the section to the storage unit affected by the relocation. For an executable file or a shared object, the value is the virtual address of the storage unit affected by the relocation.

**r\_info**—This member gives both the symbol table index with respect to which the relocation must be made, and the type of relocation to apply. For example, a call instruction's relocation entry would hold the symbol table index

---

<sup>1</sup> This virtual address is assigned during static linking. It can differ from the final execution address.

of the function being called. If the index is STN\_UNDEF, the undefined symbol index, the relocation uses 0 as the symbol value. Relocation types are processor-specific; descriptions of their behavior appear in section 4.5, *Relocation types*. When the text in section 4.5 refers to a relocation entry's relocation type or symbol table index, it means the result of applying ELF32\_R\_TYPE or ELF32\_R\_SYM, respectively, to the entry's r\_info member.

```
#define ELF32_R_SYM(i) ((i)>>8)
#define ELF32_R_TYPE(i) ((unsigned char)(i))
#define ELF32_R_INFO(s,t) (((s)<<8)+(unsigned char)(t))
```

**r\_addend**—This member specifies a constant addend used to compute the value to be stored into the relocatable field.

As shown in Figure 3-19 above, only Elf32\_Rela entries contain an explicit addend. Entries of type Elf32\_Rel store an implicit addend in the location to be modified. Depending on the processor architecture, one form or the other might be necessary or more convenient. Consequently, an implementation for a particular machine may use one form exclusively or either form depending on context.

A relocation section references two other sections: a symbol table and a section to modify. The section header's sh\_info and sh\_link members, described in section 3.3, *Sections*, above, specify these relationships. Relocation entries for different object files have slightly different interpretations for the r\_offset member.

- In re-locatable files, r\_offset holds a section offset. That is, the relocation section itself describes how to modify another section in the file; relocation offsets designate a storage unit within the second section.
- In executable and shared object files, r\_offset holds a virtual address<sup>1</sup>. To make these files' relocation entries more useful for the dynamic linker, the section offset (file interpretation) gives way to a virtual address (memory interpretation).

Although the interpretation of r\_offset changes for different object files to allow efficient access by the relevant programs, the relocation types' meanings stay the same.

## 3.7 Program view

The following subsections describe the object file information and system actions that create running programs. Executable and shared object files statically represent programs. To execute such programs, the system uses the files to create dynamic program representations, or process images. A process image has segments that hold its text, data, stack, and so on. This section describes the program header and complements preceding subsections of section 3, by describing object file structures that relate directly to program execution. The primary data structure, a program header table, locates segment images within the file and contains other information necessary to create the memory image for the program.

Given an object file, the system must load it into memory for the program to run. After the system loads the program, it must complete the process image by resolving symbolic references among the object files that compose the process.

### 3.7.1 Program Header

An executable or shared object file's program header table is an array of structures, each describing a segment or other information the system needs to prepare the program for execution (see Figure 3-20 below). An object file *segment* contains one or more *sections*. Program headers are meaningful only for executable and shared object files. A file specifies its own program header size with the ELF header's e\_phentsize and e\_phnum members [see *ELF Header* in subsection 3.2].

---

<sup>1</sup> This virtual address is assigned during static linking. It can differ from the final execution address.

**Figure 3-20, Program Header**

```
typedef struct {
    Elf32_Word p_type;
    Elf32_Off  p_offset;
    Elf32_Addr p_vaddr;
    Elf32_Addr p_paddr;
    Elf32_Word p_filesz;
    Elf32_Word p_memsz;
    Elf32_Word p_flags;
    Elf32_Word p_align;
} Elf32_Phdr;
```

**p\_type**—This member tells what kind of segment this array element describes or how to interpret the array element's information. Type values and their meanings are given in Figure 3-21, below.

**p\_offset**—This member gives the offset from the start of the file at which the first byte of the segment resides.

**p\_vaddr**—This member gives the virtual address at which the first byte of the segment resides in memory.

**p\_paddr**—On systems for which physical addressing is relevant, this member is reserved for the segment's physical address. This member requires operating system specific information.

**p\_filesz**—This member gives the number of bytes in the file image of the segment; it may be zero.

**p\_memsz**—This member gives the number of bytes in the memory image of the segment; it may be zero.

**p\_flags**—This member gives flags relevant to the segment. Defined flag values are given in Figure 3-22, below.

**p\_align**—Loadable process segments must have congruent values for p\_vaddr and p\_offset, modulo the page size. This member gives the value to which the segments are aligned in memory and in the file. Values 0 and 1 mean that no alignment is required. Otherwise, p\_align should be a positive, integral power of 2, and p\_vaddr should equal p\_offset, modulo p\_align.

Some entries describe process segments; others give supplementary information and do not contribute to the process image.

**Figure 3-21, Segment Types, p\_type**

Name	Value	Meaning
PT_NULL	0	The array element is unused; other members' values are undefined. This type lets the program header table have ignored entries.
PT_LOAD	1	The array element specifies a loadable segment, described by p_filesz and p_memsz (for additional explanation, see <b>PT_LOAD</b> below).
PT_DYNAMIC	2	The array element specifies dynamic linking information. See subsection 4.7.
PT_INTERP	3	The array element specifies the location and size of a null-terminated path name to invoke as an interpreter.
PT_NOTE	4	The array element specifies the location and size of auxiliary information.
PT_SHLIB	5	This segment type is reserved but has unspecified semantics.
PT_PHDR	6	The array element, if present, specifies the location and size of the program header table itself (for additional explanation, see <b>PT_PHDR</b> below).

**Segment Types, *p\_type* (continued)**

PT_LOPROC	0x70000000	Values in this inclusive range are reserved for processor-specific semantics.
PT_HIPROC	0x7fffffff	

**PT\_LOAD**—The bytes from the file are mapped to the beginning of the memory segment. If the segment's memory size (*p\_memsz*) is larger than the file size (*p\_filesz*), the extra bytes are defined to hold the value 0 and to follow the segment's initialized area. The file size may not be larger than the memory size. Loadable segment entries in the program header table appear in ascending order, sorted on the *p\_vaddr* member.

**PT\_PHDR**—The array element, if present, specifies the location and size of the program header table itself, both in the file and in the memory image of the program. This segment type may not occur more than once in a file. Moreover, it may occur only if the program header table is part of the memory image of the program. If it is present, it must precede any loadable segment entry.

**Note** Unless specifically required elsewhere, all program header segment types are optional. That is, a file's program header table may contain only those elements relevant to its contents.

**Figure 3-22, Defined program header flags**

Name	Value	Purpose
PF_X	1	The segment may be executed.
PF_W	2	The segment may be written to.
PF_R	4	The segment may be read.
PF_MASKPROC	0xf0000000	Reserved for processor-specific purposes (see 4.6, <i>Program headers</i> ).

**3.7.2 Note Section**

Sometimes a vendor or system builder needs to mark an object file with special information that other programs will check for conformance, compatibility, etc. Sections of type *SHT\_NOTE* and program header elements of type *PT\_NOTE* can be used for this purpose. The note information in sections and program header elements holds any number of entries, each of which is an array of 4-byte words in the format of the target processor. Labels appear below to help explain note information organization, but they are not part of the specification.

**Figure 3-23, Note Information**

namesz
descsz
type
Name
...
Desc
...

**namesz** and **name**—The first *namesz* bytes in *name* contain a null-terminated character representation of the entry's owner or originator. There is no formal mechanism for avoiding name conflicts. By convention, vendors use their own name, such as "XYZ Computer Company," as the identifier. If no name is present, *namesz* contains 0. Padding is present, if necessary, to ensure 4-byte alignment for the descriptor. Padding is not included in *namesz*.

**descsz** and **desc**—The first descsz bytes in desc hold the note descriptor. ELF places no constraints on a descriptor's contents. If no descriptor is present, descsz contains 0. Padding is present, if necessary, to ensure 4-byte alignment for the next note entry. Such padding is not included in descsz.

**type**—This word gives the interpretation of the descriptor. Each originator controls its own types; multiple interpretations of a single type value may exist. Thus, a program must recognize both the name and the type to understand a descriptor. Types currently must be non-negative. ELF does not define what descriptors mean.

To illustrate, the note segment shown in Figure 3-24, below, holds two entries.

**Note** The system reserves note information with no name (namesz==0) and with a zero-length name (name[0]=='\0') but currently defines no types. All other names must have at least one non-null character.

**Note** Note information is optional. The presence of note information does not affect a program's TIS ELF conformance, provided the information does not affect the program's execution behavior. Otherwise, the program does not conform to the TIS ELF specification and has undefined behavior.

**Figure 3-24, Example Note Segment**

	+0	+1	+2	+3

	word 1				

### 3.7.3 Program Loading

Program loading is the process by which the operating system creates or augments a process image. The manner in which this process is accomplished and how the page management functions for the process are handled are dictated by the operating system and processor. See section 4.6, *Program headers*, for more details.

### 3.7.4 Dynamic Linking

The dynamic linking process resolves references either at process initialization time and/or at execution time. Some basic mechanisms need to be set up for a particular linkage model to work, and there are ELF sections and header elements reserved for this purpose. The actual definition of the linkage model is determined by the operating system and implementation. Therefore, the contents of these sections are both operating system and processor specific. (See section 4.7, *Dynamic linking and relocation*.)

### 3.8 Special Sections Names

Various sections hold program and control information. Sections in the list below are specified in section 3 and section 4 of this specification.

**Figure 3-25, Special sections names**

.bss	.dynstr	.interp	.rodata
.comment	.dynsym	.line	.rodata1
.data	.fini	.note	.shstrtab
.data1	.got	.plt	.strtab
.debug	.hash	.rel name	.symtab
.dynamic	.init	.rela name	.text

**Figure 3-26, Dynamic Section Names**

__DYNAMIC
-----------

**Figure 3-27, Dynamic Array Tags, d\_tag**

DT_NULL	DT_NEEDED	DT_PLTRELSZ	DT_PLTGOT
DT_HASH	DT_STRTAB	DT_SYMTAB	DT_RELA
DT_RELASZ	DT_RELAENT	DT_STRSZ	DT_SYMENT
DT_INIT	DT_FINI	DT_SONAME	DT_RPATH
DT_SYMBOLIC	DT_REL	DT_RELSZ	DT_RELENT
DT_PLTREL	DT_DEBUG	DT_TEXTREL	DT_JMPREL
DT_BIND_NOW	DT_LOPROC	DT_HIPROC	

### 3.9 Pre-existing Extensions

There are naming conventions for ELF constants that have processor ranges specified. Names such as DT\_, PT\_, for processor specific extensions, incorporate the name of the processor: DT\_M32\_SPECIAL, for example. However, pre-existing processor extensions not using this convention will be supported.

**Figure 3-28, Pre-existing Extensions**

DT_JMP_REL
------------

Section names reserved for a processor architecture are formed by placing an abbreviation of the architecture name ahead of the section name. The name should be taken from the architecture names used for e\_machine. For instance .FOO.psect is the psect section defined by the FOO architecture. Existing extensions are called by their historical names.

**Figure 3-29, Pre-existing Extensions**

.sbss	.lit4	.lit8	.reginfo
.gptab	.liblist		

## 4 ARM- AND THUMB-SPECIFIC DEFINITIONS

### 4.1 ELF header

The following tables summarize the ELF header field values specific to the ARM EABI.

**Figure 4-1, ARM-specific machine and ident fields**

Field	Value and meaning
<b>e_ident</b> [EI_CLASS]	ELFCLASS32—ARM and Thumb processors use 32-bit ELF.
<b>e_ident</b> [EI_DATA]	ELFDATA2LSB           when the execution environment is little-endian. ELFDATA2MSB        when the execution environment is big-endian. (see the note immediately below).
<b>e_machine</b>	EM_ARM (decimal 40).

**Note**     The byte order of all data in an ARM ELF file is the byte order of data in the target execution environment, even if that data will only be consumed in the host (static linker) execution environment. The target byte order may differ from the host byte order.

**Figure 4-2, ARM-specific e\_flags**

Field	Value	Meaning
<b>e_flags</b>	EF_ARM_HASENTRY (0x02)	e_entry contains a program-loader entry point (see section 4.1.1, <i>Entry points</i> , below).
	EF_ARM_SYMSARESORTED (0x04)	Each subsection of the symbol table is sorted by symbol value (see section 4.4.8, <i>Symbol table order</i> , below)
	EF_ARM_DYNSYMSUSESEGIDX (0x08)	Symbols in dynamic symbol tables that are defined in sections included in program segment <i>n</i> have st_shndx = <i>n</i> + 1. (see section 4.4.9, <i>Dynamic symbol table entries</i> , below).
	EF_ARM_MAPSYMSFIRST (0x10)	Mapping symbols precede other local symbols in the symbol table (see section 4.4.8, <i>Symbol table order</i> , below).
	EF_ARM_EABIMASK (0xFF000000) (current version is 0x02000000)	This masks an 8-bit version number, the version of the ARM EABI to which this ELF file conforms. This EABI is version 2. A value of 0 denotes unknown conformance.

**Figure 4-3, Interpretation of the entry point**

Field	Value and meaning
<b>e_entry</b> (see section 4.1.1, <i>Entry points</i> , below).	In an executable ELF file, e_entry is the virtual address of the image's unique entry point, or 0 if the image does not have a unique entry point.  In a re-locatable ELF file, e_entry is the offset of the entry point in the section flagged by SHF_ENTRYSECT or 0 if there is no entry point.

### 4.1.1 Entry points

*Entry point* means a location to which control may be transferred by the execution environment.

A program can have many entry points—for example, corresponding to reset, interrupt, software interrupt, undefined instruction exception, and so on. A program loader cannot start such a program. A shared object usually has no entry point. Again, a loader cannot start execution.

An ELF executable that can be started by a program loader must have an entry address. It can be 0. EF\_ARM\_HASENTRY distinguishes an entry address of 0 from no program loader entry address. Consumers should accept a non-zero entry address, or a zero entry address with EF\_ARM\_HASENTRY set in e\_flags. Producers should set EF\_ARM\_HASENTRY if the executable has an entry point.

In a re-locatable ELF file:

- The section containing an entry point is flagged by SHF\_ENTRYSECT (see section 4.3, *Section headers*).
- The ELF header field e\_entry gives the offset of the entry point in that section.
- There can be at most one entry point in a re-locatable ELF file.

In an ARM executable ELF file, several program segments can be mapped at the same virtual address so:

- The program segment containing the entry address is flagged by PF\_ARM\_ENTRY (see section 4.6, *Program headers*).

## 4.2 Section names

An ARM section name is one that begins with one of the standard prefixes listed below that have pre-defined meanings, or a name containing a dollar (\$) character. No other section names have special significance under the ARM EABI.

**Note** Bracketed SHF\_ALLOC flags are set only if the section is contained in an executable program segment (one of type PT\_LOAD or PT\_DYNAMIC—see section 4.6, *Program headers*).

**Note** There can be many sections with the same name in an ELF file.

**Figure 4-4, ARM standard section names and their meanings**

Name prefix	Section type	Section attributes	Explanation
.bss	SHT_NOBITS	SHF_ALLOC+SHF_WRITE	Uninitialized data—set to zero before execution.
.comment	SHT_PROGBITS	None	A comment from the producing tool—version data.
.data	SHT_PROGBITS	SHF_ALLOC+SHF_WRITE	Initialized data.
.debug...	SHT_PROGBITS	None	Debugging tables (may include line number data).
.dynamic	SHT_DYNAMIC	SHF_ALLOC [+SHF_WRITE]	Dynamic linking information—may not be writable.
.dynsym	SHT_DYNSYM	[SHF_ALLOC]	A symbol table for dynamic linking.
.hash	SHT_HASH	[SHF_ALLOC]	A symbol hash table.
.line	SHT_PROGBITS	None	Line number data for debugging.
.rodata	SHT_PROGBITS	SHF_ALLOC	Initialized read-only data.

**ARM standard section names and their meanings (continued)**

.relname .relaname	SHT_REL SHT_RELA	[SHF_ALLOC]	Relocation data. By convention, the continuation of the name is the name of the section being relocated.
.shstrtab	SHT_STRTAB	None	The section name string table.
.strtab	SHT_STRTAB	[SHF_ALLOC]	A string table for a symbol table.
.symtab	SHT_SYMTAB	[SHF_ALLOC]	A symbol table for static linking.
.text	SHT_PROGBITS	SHF_ALLOC+ SHF_EXECINSTR	Program instructions and inline literal data.

**4.3 Section headers****Figure 4-5, ARM-EABI-specific values for sh\_flags**

Name	Value	Purpose
SHF_ENTRYSECT	0x10000000	The section contains an entry point (see section 4.1.1, <i>Entry points</i> ).
SHF_COMDEF	0x80000000	The section may be multiply defined in the input to a link step (see section 4.3.1, <i>Common sections</i> ).

**4.3.1 Common sections**

The SHF\_COMDEF attribute denotes that there may be multiple definitions of this section. From each set of identically named sections having the SHF\_COMDEF attribute, the linker retains only one representative (but it retains all identically named sections *not* having the SHF\_COMDEF attribute).

Object producers must ensure that it does not matter which variant of a common section is retained. In general, this requires:

- ☐ All variants of a common section must define the same global symbols.
- ☐ If the section contains code, all variants must have the same functional interface. However, different variants may have a different size, a different content, or be differently relocated.
- ☐ If the section contains data, all variants must have the same size, the same content, and be similarly relocated.

This specification does not define which variant of a common section a linker should retain.

**4.3.2 Section alignment**

The ARM EABI requires that each executable section must be aligned on a 4-byte boundary. Any section having the SHF\_ALLOC attribute must have `sh_addralign`  $\geq 4$ . Other sections can be aligned as required. For example, debugging tables usually have no alignment requirements, and data sections input to a static linker can be naturally aligned.

### 4.3.3 Link and info fields

**Figure 4-6, Interpretation of *sh\_link* and *sh\_info***

sh_type	sh_link	sh_info
SHT_SYMTAB, SHT_DYNSYM	The section header index of the associated string table.	One more than the symbol table index of the last local symbol (the last one with binding STB_LOCAL).

## 4.4 Symbols

### 4.4.1 Symbol value

See also section 3.5.1, *Symbol Values*.

In a re-locatable file:

- For a COMMON symbol defined in the SHN\_COMMON section, st\_value gives its alignment constraint (the allocated address of the symbol must be zero modulo st\_value).
- For a symbol definition, st\_value gives its offset within the section identified by st\_shndx.

In executable and shared object files:

- For symbols defined in sections included in executable program segments, st\_value is a target-system virtual address assigned when the ELF file is statically linked.
- Otherwise, st\_value is a virtual address in an address space specific to the operating environment (for example, symbols defined in debugging tables).

### 4.4.2 Symbol size

For a symbol definition of type STT\_FUNC, st\_size gives the length of the function in bytes, or 0 if this is unknown.

For a symbol definition of type STT\_OBJECT, st\_size gives the length in bytes of the associated data object or 0 if this is unknown.

### 4.4.3 Weak symbols

No library is searched to satisfy an undefined weak symbol (st\_shndx = SHN\_UNDEF, ELF32\_ST\_BIND = STB\_WEAK), or *weak reference*. It is not an error for a weak reference to remain unsatisfied.

The value of an undefined weak symbol is:

- $P + 4$  if location  $P$  is subject to branch relocation (R\_ARM\_PC24, R\_ARM\_THM\_PC22, R\_ARM\_XPC25, R\_ARM\_THM\_XPC22).
- $P$  if location  $P$  is subject to a PC-relative or SB-relative relocation.
- Otherwise, 0.

You can think of these values as branch offset 0 (branch to the next instruction), offset 0, and absolute 0, respectively. That is, the value of an undefined weak symbol is always the sort of 0 appropriate to the relocation directive referring to it.

A weak symbol definition may coexist with a non-weak definition, but all references to the symbol resolve to the non-weak definition.

A file may make both a weak reference and a non-weak reference through distinct symbols that have the same name (this can help a linker perform unused section elimination).

#### 4.4.4 Symbol names

A symbol that names a C or assembly language entity should have the name of that entity. For example, a C function called *calculate* generates a symbol called *calculate* (not *\_calculate*).

C++ and Java follow their own language-specific rules.

All symbol names containing a dollar character ('\$') are reserved to the ARM EABI.

Symbol names are case sensitive and are matched exactly by linkers.

#### 4.4.5 Sub-class and super-class symbols

A symbol `$Sub$name` is the sub-class version of *name*. A symbol `$Super$name` is the super-class version of *name*. In the presence of a definition of both *name* and `$Sub$name`:

- A reference to *name* resolves to the definition of `$Sub$name`.
- A reference to `$Super$name` resolves to the definition of *name*.

It is an error to refer to `$Sub$name`, or to define `$Super$name`, or to use `$Sub$...` or `$Super$...` recursively.

#### 4.4.6 Function address constants and pointers to code

The address of an ARM function is a multiple of 4. So is the `st_value` field of a symbol labeling an ARM-state code address.

The address of a Thumb function is a multiple of 2. So is the `st_value` field of a symbol labeling a Thumb-state code address.

Nonetheless, wherever a Thumb function address is crystallized in memory, the least significant bit of the address should be set. This allows a call from either instruction-set state to execute the pointed-to function in Thumb-state.

In practice, a linker must set the Thumb-state bit (bit 0 of the address) whenever it relocates a data value with respect to a Thumb-state code symbol.

#### 4.4.7 Mapping and tagging symbols

A section of an ARM ELF file can contain a mixture of ARM code, Thumb code, and data.

There are inline transitions between code and data at literal pool boundaries. There can also be inline transitions between ARM code and Thumb code, for example in ARM-Thumb inter-working veneers.

Linkers, machine-level debuggers, profiling tools, and disassembly tools need to map images accurately. For example, setting an ARM breakpoint on a Thumb location, or in a literal pool, can crash the program being debugged, ruining the debugging session.

ARM ELF entities are mapped (see section 4.4.7.1 below) and tagged (see section 4.4.7.2 below) using local symbols (with binding `STB_LOCAL`).

To assist consumers, mapping and tagging symbols should be collated first in the symbol table, before other symbols with binding `STB_LOCAL`.

To allow properly collated mapping and tagging symbols to be skipped by consumers that have no interest in them, the first such symbol should have the name `$m` and its `st_value` field equal to the total number of mapping and tagging symbols (including the `$m`) in the symbol table.

#### 4.4.7.1 Mapping symbols

- \$a labels the first byte of a sequence of ARM instructions. Its type is STT\_FUNC.
- \$d labels the first byte of a sequence of data items. Its type is STT\_OBJECT.
- \$t labels the first byte of a sequence of Thumb instructions. Its type is STT\_FUNC.

This list of mapping symbols may be extended in the future.

#### **Section-relative mapping symbols**

Mapping symbols defined in a section define a sequence of half-open address intervals that cover the address range of the section. Each interval starts at the address defined by a mapping symbol, and continues up to, but not including, the address defined by the next (in address order) mapping symbol or the end of the section. A corollary is that there must be a mapping symbol defined at the beginning of each section.

Consumers can ignore the size of a section-relative mapping symbol. Producers can set it to 0.

#### **Absolute mapping symbols**

Because of the need to crystallize a Thumb address with the Thumb-bit set, absolute symbol of type STT\_FUNC (symbols of type STT\_FUNC defined in section SHN\_ABS) need to be mapped with \$a or \$t.

The extent of a mapping symbol defined in SHN\_ABS is [st\_value, st\_value + st\_size), or [st\_value, st\_value + 1) if st\_size = 0, where [x, y) denotes the half-open address range from x, inclusive, to y, exclusive.

In the absence of a mapping symbol, a consumer can interpret a function symbol with an odd value as the Thumb code address obtained by clearing the least significant bit of the value. This interpretation is deprecated, and it may not work in the future.

#### 4.4.7.2 Tagging symbols

Tagging symbols help consumers by tagging specific entities in a program. In each case, a consumer can ignore the size of a tagging symbol. A producer should set the size to the size of the tagged entity or 0.

- \$b labels a Thumb BL instruction. Its type is STT\_FUNC, its size is 4 bytes.
- \$f labels a function pointer constant (static pointer to code). Its type is STT\_OBJECT, its size is 4 bytes.
- \$p labels the final, PC-modifying instruction of an indirect function call. Its type is STT\_FUNC. (An indirect call is a call through a function pointer variable). \$p *does not* label the PC-modifying instruction of a function return sequence. Its size is 2 bytes in Thumb-state, 4 bytes in ARM-state.
- \$m gives (in its st\_value field) the total number of mapping and tagging symbols in the symbol table.

This list of tagging symbols is not exhaustive and others may be defined in the future.

#### 4.4.8 Symbol table order

The order of symbols in the symbol table should be:

- ☐ Local symbols
  - \$m
  - Other mapping and tagging symbols sorted in virtual address order
  - Other local symbols sorted in virtual address order (save that each symbol of type STT\_FILE should precede all the symbols of type STT\_SECTION that are associated with it).
- ☐ Global symbols.

If the `EF_ARM_MAPSYMSFIRST` flag is set in the `e_flags` field of the ELF header (see section 4.1, *ELF header*):

A consumer can rely on mapping and tagging symbols preceding other local symbols.

The first local symbol will have the name **\$m** and its `st_value` field will be equal to the total number of mapping and tagging symbols (including the \$m) in the symbol table.

Otherwise, a consumer must assume that mapping symbols are interleaved with other local symbols.

If `EF_ARM_SYMSARESORTED` is set in the `e_flags` field of the ELF header (see section 4.1, *ELF header*):

Each subsection of the symbol table is sorted by increasing `st_value` (symbols of type `STT_FILE` excepted).

Each symbol of type `STT_FILE` precedes all the symbols of type `STT_SECTION` associated with it (thus a consuming debugger can easily map each image section to the source file it was created from).

Otherwise, a consumer should not assume that symbol table subsections are sorted by address.

#### 4.4.9 Dynamic symbol table entries

In a linkable object file, a symbol is defined in a section of type `SHT_SYMTAB`. In an executable or shared object file, a dynamic symbol table is defined in the dynamic program segment (see section 4.7.1 *The dynamic segment*, below). A section view of an executable or shared object file is optional. When the section-relative interpretation of a symbol's value gives way to the virtual address interpretation, it is useful to know in which program segment a symbol is defined if, for example, this is not uniquely determined by the symbol's virtual address.

Under the ARM EABI, a symbol in a dynamic symbol table (a `.dynsym` section) that is defined in a section included in program segment  $n$  has `st_shndx = n + 1`.

`EF_ARM_DYNSYMSUSESEGIDX` is set in the `e_flags` field of the ELF header (see section 4.1, *ELF header*) to tell consumers that `st_shndx` identifies the program segment in which the symbol is defined.

### 4.5 Relocation types

ELF defines two sorts of relocation directive, `SHT_REL`, and `SHT_RELA`. Both identify:

- A *section* containing the storage unit—byte, half-word, word, or instruction—being relocated.
- An *offset* within the section—or the address within an executable program—of the storage unit itself.
- A *symbol*, the value of which helps to define a new value for the storage unit.
- A relocation *type* that defines the computation to be performed. Computations are performed using 2's complement, 32-bit, unsigned arithmetic with silent overflow.
- An *addend*, that also helps to define a new value for the storage unit.

The addend may be encoded wholly in a field of the storage unit being relocated—relocation sort `SHT_REL`—or partly there and partly in the *addend* field of the relocation directive—relocation sort `SHT_RELA`.

Tables below describe the computation associated with each relocation type, using the following notation:

- A** denotes the addend used to compute the new value of the storage unit being relocated.
  - It is the value extracted from the storage unit being relocated (relocation directives of sort `SHT_REL`) or the sum of that value and the `r_addend` field of the relocation directive (sort `SHT_RELA`).
  - If it has a unit, the unit is bytes. An encoded address or offset value is converted to bytes on extraction from a storage unit and re-encoded on insertion into a storage unit.
- P** denotes the place (section offset or address of the storage unit) being re-located. It is the sum of the `r_offset` field of the relocation directive and the base address of the section being re-located.

- S** denotes the value of the symbol whose symbol table index is given in the `r_info` field of the relocation directive.
- B** denotes the base address of the consolidated section in which the symbol is defined. For relocations of type `R_ARM_SBREL32`, this is the least static data address (the static base).

**Figure 4-7, ARM relocation types 0-16**

Type	Name	Field	Computation and meaning
0	<code>R_ARM_NONE</code>	Any	No relocation. Encodes dependencies between sections.
1	<code>R_ARM_PC24</code>	ARM B/BL	$S - P + A$
2	<code>R_ARM_ABS32</code>	32-bit word	$S + A$
3	<code>R_ARM_REL32</code>	32-bit word	$S - P + A$
4	<code>R_ARM_PC13</code>	ARM LDR r, [pc,...]	$S - P + A$
5	<code>R_ARM_ABS16</code>	16-bit half-word	$S + A$
6	<code>R_ARM_ABS12</code>	ARM LDR/STR	$S + A$
7	<code>R_ARM_THM_ABS5</code>	Thumb LDR/STR	$S + A$
8	<code>R_ARM_ABS8</code>	8-bit byte	$S + A$
9	<code>R_ARM_SBREL32</code>	32-bit word	$S - B + A$
10	<code>R_ARM_THM_PC22</code>	Thumb BL pair	$S - P + A$
11	<code>R_ARM_THM_PC8</code>	Thumb LDR r, [pc,...]	$S - P + A$
12	<code>R_ARM_AMP_VCALL9</code>	<i>AMP VCALL</i>	<i>Obsolete—SA-1500 only.</i>
13	<code>R_ARM_SWI24</code>	ARM SWI	$S + A$
14	<code>R_ARM_THM_SWI8</code>	Thumb SWI	$S + A$
15	<code>R_ARM_XPC25</code>	ARM BLX	$S - P + A$
16	<code>R_ARM_THM_XPC22</code>	Thumb BLX pair	$S - P + A$

**Note** A relocation directive of type `R_ARM_NONE` records that the section containing the place to be relocated depends on the section defining the symbol mentioned in the relocation directive in a way otherwise invisible to a static linker. It therefore prevents the removal of sections that might appear to be unused.

**Figure 4-8, ARM relocation types 17-31, reserved to ARM Linux**

Type	Name	Field	Computation and meaning
17-19			Reserved to ARM LINUX
20	<code>R_ARM_COPY</code>	32 bit word	Copy symbol at dynamic link time.
21	<code>R_ARM_GLOB_DAT</code>	32 bit word	Create GOT entry.
22	<code>R_ARM_JUMP_SLOT</code>	32 bit word	Create PLT entry.

**ARM relocation types 17-31, reserved to ARM Linux (continued)**

23	R_ARM_RELATIVE	32 bit word	Adjust by program base.
24	R_ARM_GOTOFF	32 bit word	Offset relative to start of GOT.
25	R_ARM_GOTPC	32 bit word	Insert address of GOT.
26	R_ARM_GOT32	32 bit word	Entry in GOT.
27	R_ARM_PLT32	ARM BL	Entry in PLT.
28-31			Reserved to ARM LINUX

112-127	To be defined	To be defined	Reserved for private experiments—These values will never clash with relocations defined by ARM, but will always clash with other private experiments.

**Figure 4-12, ARM relocation types 128-248, reserved to ARM**

Type	Name	Field	Computation and meaning
128-248			Reserved to ARM

#### 4.5.1 Dynamic relocation types

A small set of relocation types supports relocating executable ELF files. They are used only in a relocation section embedded in a dynamic segment (see section 4.7, *Dynamic linking and relocation*). They cannot be used in a relocation section in a re-locatable ELF file. In Figure 4-13 below:

- $\Delta S$**  is the displacement from its statically linked virtual address of the segment containing the symbol definition.
- $\Delta P$**  is the displacement from its statically linked virtual address of the segment containing the place to be relocated.
- $\Delta SB$**  is the displacement of the segment pointed to by the static base (PF\_ARM\_SB is set in the p\_flags field of this segment's program header—see 4.6, *Program headers*).

**Figure 4-13, ARM dynamic relocation types 249-255**

Type	Name	Field	Computation and meaning
249	R_ARM_RXPC25	ARM BLX	$(\Delta S - \Delta P) + A$ For calls between program segments.
250	R_ARM_RSBREL32	Word	$(\Delta S - \Delta SB) + A$ For an offset from SB, the static base.
251	R_ARM_THM_RPC22	Thumb BL/BLX pair	$(\Delta S - \Delta P) + A$ For calls between program segments.
252	R_ARM_RREL32	Word	$(\Delta S - \Delta P) + A$ For on offset between two segments.
253	R_ARM_RABS32	Word	$\Delta S + A$ For the address of a location in the target segment.
254	R_ARM_RPC24	ARM B/BL	$(\Delta S - \Delta P) + A$ For calls between program segments.
255	R_ARM_RBASE	None	None—Identifies the segment being relocated by the following relocation directives.

The ARM EABI poses two problems for relocating executables and shared objects encoded in ELF:

- An executable or shared-object ELF file can contain many program segments that can be placed independently in memory when the file is loaded. To support this, a static linker must either:
  - Defer until load time relocations that depend on segment addresses.
  - Or, reduce such relocations to a simpler form that depends only on segment addresses (or, equivalently, on the displacements of segments from their statically linked addresses).
- Program segments can be overlaid in the target address space. Consequently, a virtual address does not uniquely identify a place to be relocated.

The `R_ARM_RBASE` type informs a consumer that following relocation directives relocate places in the segment (the *source* segment) identified by its `ELF32_R_SYM` field:

- If `ELF32_R_SYM = n > 0`, following relocations apply to source segment (n-1).
- If `ELF32_R_SYM = n = 0`, following relocations identify the source segment by virtual address only.

Consumers can ignore the `r_offset` field. Producers should set it to zero.

Prior to the first `R_ARM_RBASE` directive, relocation directives identify the source segment by virtual address.

### ***Displacement-based dynamic relocation types***

The ARM EABI defines displacement-based dynamic relocation types. Their advantage is that if an ELF file contains only dynamic relocations and each program segment is loaded at its statically linked address, there is no relocation work to do at load time.

For the remaining dynamic relocation types:

- The `r_offset` field gives the virtual address of the place being relocated. Its offset in the source segment is the difference between `r_offset` and the statically linked address of the source segment.
- `ELF32_R_SYM - 1` indexes the program segment (the *target* segment) with respect to which the place is being re-located.

`R_ARM_RABS32` directs a consumer to add to the place the displacement of the target segment from its statically linked virtual address.

`R_ARM_RPC24`, `R_ARM_RXPC25`, `R_ARM_RREL32`, and `R_ARM_THM_RPC22` direct a consumer to add to the place the difference between the displacement of the target segment (from its statically linked virtual address) and the displacement of the source segment (from its statically linked virtual address).

`R_ARM_RSBREL32` is similar to `R_ARM_RREL32`, except that the segment addressed by the static base register is used as the source segment (the `PF_ARM_SB` flag is set in the `p_flags` field of this program segment's header. See section 4.6, *Program headers*).

PC-relative re-location is defined using the difference of two displacements to support the displacement of a program by more than the maximum BL offset.

Re-location may fail at load time if program segments are moved apart too much—beyond the address range of a BL instruction, for example.

## **4.5.2 Multiple relocation**

A field can be relocated many times, but this cannot be exploited to generate a compound relocation because an intermediate step may overflow, even when the compound relocation would not (consider, for example, adding 0x1000004 to, then subtracting 0x1000000 from, a 16-bit field).

## **4.5.3 Field extraction and insertion**

The byte order of a field in an ELF file is its byte order in the target execution environment. This may differ from the byte order in the host (linker) execution environment.

ARM instructions are 4-byte aligned (relocation types 1, 4, 6, 12, 13, 15, 32-37). Thumb instructions are 2-byte aligned (relocation types 7, 10, 11, 14, 16, 102-103).

Other fields have no alignment requirement. For example, a 4-byte field (relocation types 2, 3, and 9) may occur at any address.

An ARM ELF consumer never needs to interpret an instruction word to determine how to relocate it. The sub-fields to relocate and the unit of relocation (byte, half word, word, or double word) are evident from the relocation type.

Labeling the least significant bit of a 32-bit ARM instruction word, or 16-bit Thumb instruction word, *bit 0*, instruction fields to be relocated are given in Figure 4-14 and Figure 4-15, below.

**Figure 4-14, Re-locatable ARM instruction fields**

R_ARM_PC24	Bits 0-23 encode a signed offset, in units of 4-byte instructions (thus 24 bits encode a branch offset of $\pm 2^{25}$ bytes).
R_ARM_PC13	Bits 0-11 encode an unsigned byte offset. Bit 23 encodes the direction of the offset—0 means to a lower address than P, 1 to a higher address.
R_ARM_ABS12	Bits 0-11 encode an unsigned byte offset.
R_ARM_SWI24	Bits 0-23 encode the ARM SWI number.
R_ARM_XPC25	Bits 0-23 encode a signed offset in units of 4-byte words. Bit 24 encodes bit 1 of the target Thumb address.
R_ARM_ALU_PCREL_7_0, R_ARM_ALU_PCREL_15_8, R_ARM_ALU_PCREL_23_15	Bits 0-7 contain the bit value of the selected field. Bits 8-11 contain 0, 0xc, or 0x8, half the rotate-right needed to shift the value to its field position. Bits 23 and 22 encode the sign of the value—01 means negative, 10 means positive.
R_ARM_LDR_SBREL_11_0	Bits 0-11 contain the bit value of the selected field. Bit 23 encodes the sign of the value—0 means negative, 1 means positive.
R_ARM_ALU_SBREL_19_12, R_ARM_ALU_SBREL_27_20	Bits 0-7 contain the bit value of the selected field. Bits 8-11 contain 0xa or 0x6, half the rotate-right needed to shift the value to its field position. Bits 23 and 22 encode the sign of the value—01 means negative, 10 means positive.

**Figure 4-15, Re-locatable Thumb instruction fields**

R_ARM_THM_ABS5	Bits 6-10 encode a 5-bit unsigned offset in units of 4-byte words (Thumb LDRB/LDRH cannot be relocated).
R_ARM_THM_PC22	Bits 0-10 encode the 11 most significant bits of the branch offset. Bits 0-10 of the next instruction word encode the 11 least significant bits. The unit is 2-byte instructions.
R_ARM_THM_PC8	Bits 0-7 encode an 8-bit unsigned offset in units of 4-byte words. An initial offset of 255 must be interpreted as an offset of $-1$ (so the initial offset range is $[-1, 254]$ ).
R_ARM_THM_SWI8	Bits 0-7 encodes the Thumb SWI number.
R_ARM_THM_XPC22	Bits 0-10 encode the 11 most significant bits of the branch offset. Bits 1-10 of the next instruction word encode the bits 1-10 of the branch offset. Bit 0 must be set to 0. The unit is 2-byte instructions.

**Note** When a Thumb LDR [pc, ...] instruction is subject to a REL-sort relocation of type R\_ARM\_THM\_PC8, there must be a way to encode the offset to the place containing the instruction in the initial value of the instruction. Using the value 255 to encode  $-1$  does this.

#### 4.5.4 Relocations that depend on the type of the target location

As explained in section 4.4.6, *Function address constants and pointers to code*, the address of a Thumb function must have bit 0 set to 1. Bit 0 must be set whenever the location to which the relocated place points (the target location) is mapped (see section 4.4.7, *Mapping and tagging symbols*) as Thumb code.

## 4.6 Program headers

**Figure 4-16, Program header fields for ARM executables**

Field	Value and meaning
<b>p_type</b>	PT_LOAD (= 1) for each segments that is part of the memory image. PT_DYNAMIC (= 2) for the dynamic segment (see 4.7.1, <i>The dynamic segment</i> ).
<b>p_offset</b>	The offset of the segment in the file. This must be 0 modulo 4.
<b>p_vaddr</b>	The virtual address at which the segment should be loaded. This must be 0 modulo 4.
<b>p_paddr</b>	Unused in the ARM EABI. Set to zero by ARM tools.
<b>p_filesz</b>	The number of bytes in the file image of the segment; it may be zero.
<b>p_memsz</b>	The number of bytes in the memory image of the segment; it may be zero.
<b>p_flags</b>	Any combination of PF_X, PF_R, PF_W, PF_ARM_SB, PF_ARM_PI, PF_ARM_ENTRY (see Figure 4-17, <i>Program header flags</i> , below).
<b>p_align</b>	A power of 2 greater than or equal to 4 (4, 8, 16, 32, and so on). (ARM and Thumb loadable segments are at least word-aligned).

**Note** Each segment of an executable is statically linked at some virtual address. Unless the segment is position independent, re-locatable, or self-relocating, this is where the segment will execute.

**Note** When p\_align records the alignment required by the contents of the segment, p\_offset and p\_vaddr must be 0 modulo p\_align. When p\_align records a page size greater than this alignment, p\_offset and p\_vaddr are merely congruent modulo p\_align (see section 3.7.1, *Program Header*).

**Figure 4-17, Program header flags**

Flag Name	Value	Meaning
PF_X	0x1	The program will fetch instructions from the segment.
PF_R	0x2	The program will read data from the segment.
PF_W	0x4	The program will write to the segment.
PF_ARM_SB	0x10000000	The segment contains the location addressed by the static base.
PF_ARM_PI	0x20000000	The segment is position-independent.
PF_ARM_ENTRY	0x80000000	The segment contains the entry point.

**Note** PF\_ARM\_ENTRY is set in a program header if that program segment contains the entry point virtual address. The meaning is unspecified if PF\_ARM\_ENTRY is set in more than one program header, or PF\_ARM\_ENTRY is set in no program header and more than one segment contains the entry point address.

**Note** Flag settings encode an assertion about the executable segment by its producer. A consumer should grant the least access consistent with the segment's requirements.

**Note** In general, an ARM and Thumb executable segment must also be readable. A limited PC-relative addressing range virtually mandates that instructions and literal data are interleaved in a segment.

## 4.7 Dynamic linking and relocation

A dynamically linked executable or shared object undergoes its final stage of linking when it is:

- Loaded into memory by a program loader.
- Prepared for ROM by a ROM builder.

An executable or shared object to be linked dynamically may:

- List one or more shared objects (shared libraries) with which it should be linked.
- Refer to symbols defined by these shared objects, the execution environment, or the ROM builder. These references appear as undefined symbols in the dynamic symbol table.
- Define symbols that can be referred to by these shared objects, the execution environment, or the ROM builder. These symbols are defined in the dynamic symbol table.
- List locations to be relocated whose values depend on:
  - The actual execution addresses given to program segments.
  - The values of symbols defined during dynamic linking.

In general, some storage units will need to be relocated when symbolic references are resolved.

### 4.7.1 The dynamic segment

If an ARM executable or shared object needs dynamic linking, or is re-locatable, it contains a program segment of type PT\_DYNAMIC. The dynamic segment contains:

- A dynamic section (see 4.7.3, *The dynamic section*) that describes the dynamic segment.
- A string table used by the symbol table and directly by some dynamic section entries (see 3.4, *String Table*).
- A dynamic symbol table section. This has the same format as a symbol table (see 3.5, *Symbol Table*), but may use a different interpretation of st\_shndx (see 4.4.9, *Dynamic symbol table entries*).
- A section containing relocations (a section of sort SHT\_REL and/or SHT\_RELA). This has the same format as any other relocation section (see 3.6, *Relocation*).
- A hash table that accelerates use of the symbol table (see 4.7.4, *The hash table section*).

Optionally, section headers of the following types may describe these sub-sections of the dynamic segment:

- SHT\_DYNAMIC—the dynamic array itself.
- SHT\_STRTAB—the string table.
- SHT\_DYNSYM—the symbol table.
- SHT\_REL and/or SHT\_RELA—the relocation section(s).
- SHT\_HASH—the symbol hash table.

Dynamic linkers do not use this section view.

### 4.7.2 The dynamic segment program header

The dynamic segment program header has p\_type = PT\_DYNAMIC (= 2).

The ARM EABI defines no meaning for the following fields of the program header of a dynamic segment:

- p\_vaddr, p\_paddr, p\_memsz, p\_align.
- The PF\_MASKPROC sub-field of p\_flags.

Operating environments are free to define their own semantics for these fields.

### 4.7.3 The dynamic section

The dynamic segment begins with a dynamic section containing an array of structures of type:

```
typedef struct Elf32_Dyn {
    Elf32_Sword d_tag;
    Elf32_Word  d_val;
} Elf32_Dyn;
```

Each element is self-identifying through its `d_tag` field.

**Figure 4-18, Dynamic section tags**

d_tag	Tag name	The value of d_val and the meaning of the array entry	Status
0	DT_NULL	Ignored. This entry marks the end of the dynamic array.	mandatory
1	DT_NEEDED	Index in the string table of the name of a needed library.	multiple
2	DT_PLTRELSZ	These entries are unused by versions 1-2 of the ARM EABI.	unused
3	DT_PLTGOT		
4	DT_HASH	The offset of the hash table section in the dynamic segment.	mandatory
5	DT_STRTAB	The offset of the string table section in the dynamic segment.	mandatory
6	DT_SYMTAB	The offset of the symbol table section in the dynamic segment.	mandatory
7	DT_RELA	The offset in the dynamic segment of an SHT_RELA relocation section, its byte size, and the byte size of an ARM RELA-type relocation entry.	optional
8	DT_RELASZ		
9	DT_RELAENT		
10	DT_STRSZ	The byte size of the string table section.	mandatory
11	DT_SYMENT	The byte size of an ARM symbol table entry—16.	mandatory
12	DT_INIT	These entries are unused by versions 1-2 of the ARM EABI.	unused
13	DT_FINI		
14	DT_SONAME	The Index in the string table of the name of this shared object.	mandatory
15	DT_RPATH	Unused by the ARM EABI.	unused
16	DT_SYMBOLIC		
17	DT_REL	The offset in the dynamic segment of an SHT_REL relocation section, its byte size, and the byte size of an ARM REL-type relocation entry	optional
18	DT_RELSZ		
19	DT_RELENT		
20	DT_PLTREL	These entries are unused by versions 1-2 of the ARM EABI.	unused
21	DT_DEBUG		
22	DT_TEXTREL		
23	DT_JMPREL		
24	DT_BIND_NOW		
0x70000000	DT_LOPROC	Values in this range are reserved to the ARM EABI.	unused
0x7fffffff	DT_HIPROC		

**Note** The last entry in the dynamic array must have tag `DT_NULL`.

**Note** The relative order of `DT_NEEDED` entries may be important to a dynamic linker. Otherwise the order of entries in the dynamic array has no significance.

**Note** A DT\_SONAME entry is mandatory only for shared objects, not for dynamically linked executables.

Following the dynamic array, the dynamic segment includes:

- A hash table section (see 4.7.4, *The hash table section*).
- A symbol table section (called *.dynsym* in the section view—see 3.5, *Symbol Table*).
- A string table section (see 3.4, *String Table*).
- Relocation sections (see 3.6, *Relocation*).

The order of these sections is unimportant. The offset of each in the dynamic segment is given by the corresponding entry in the dynamic array.

#### 4.7.4 The hash table section

The hash table section is described by the following pseudo-C structure:

```
struct Elf32_HashTable {
    Elf32_Word nBuckets;
    Elf32_Word nChains;
    Elf32_Word bucket[nBuckets];
    Elf32_Word chain[nChains];
};
```

Both *bucket* and *chain* hold symbol table indexes. Indexes start at 0. *Bucket* can have any convenient size. There is one chain entry for each symbol in the symbol table (*nChains* = number of symbols).

*Bucket* and *chain* implement a chained overflow hash table access structure for the symbol table. If *h* is the result of applying the ELF hash function (see Figure 4-19, *The ELF hash function*) to a symbol's name, the start of the chain of symbols that hash to this bucket is given by:

```
bucket[h % nBuckets]
```

For each symbol index *s*, *chain[s]* gives the index of the next symbol that hashes to the same bucket. Zero indexes the dummy symbol and is used as the end of chain pointer.

**Figure 4-19, The ELF hash function**

```
unsigned long elf_hash(const unsigned char *name)
{
    unsigned long h, g;

    for (h = 0; *name != 0; ++name)
    {
        h = (h << 4) + *name;
        g = h & 0xf0000000;
        if (g != 0) h ^= g >> 24;
        h &= ~g;
    }
    return h;
}
```
